Problem 1: Richest Customer Wealth (easy)

Problem Statement

Given a 2D array `accounts` of `m x n` size, `accounts[j]` represents money in the `jth` bank account of the `ith` customer.

Return the wealth of the richest individual from a set of bank customers.

Imagine every customer has multiple bank accounts, with each account holding a certain amount of money. The total wealth of a customer is calculated by summing all the money across their multiple accounts.

Examples

1. **Example 1**:
   - **Input**: `[[5,2,3],[0,6,7]]`
   - **Expected Output**: `13`
   - **Justification**: The total wealth of the first customer is 10 and of the second customer is 13. So, the output is 13 as it's the maximum among all customers.
2. **Example 2**:
   - **Input**: `[[1,2],[3,4],[5,6]]`
   - **Expected Output**: `11`
   - **Justification**: Total wealth for each customer is [3, 7, 11]. Maximum of these is 11.
3. **Example 3**:
   - **Input**: `[[10,100],[200,20],[30,300]]`
   - **Expected Output**: `330`
   - **Justification**: Total wealth for each customer is [110, 220, 330]. The wealthiest customer has 330.

Try it yourself

Try solving this question here:

Java

```java
class Solution {
    public static int maximumWealth(int[][] accounts) {
        int maxWealth = 0;  // Initialize maxWealth to 0
        // ToDo: Write Your Code Here.
        return maxWealth;
    }
}
```

Test Case | Run Code Result | Stdout

[[5,15,25],[10,20,30],[0,0,0]]
