The Architecture of the BFF Pattern

The Blueprint

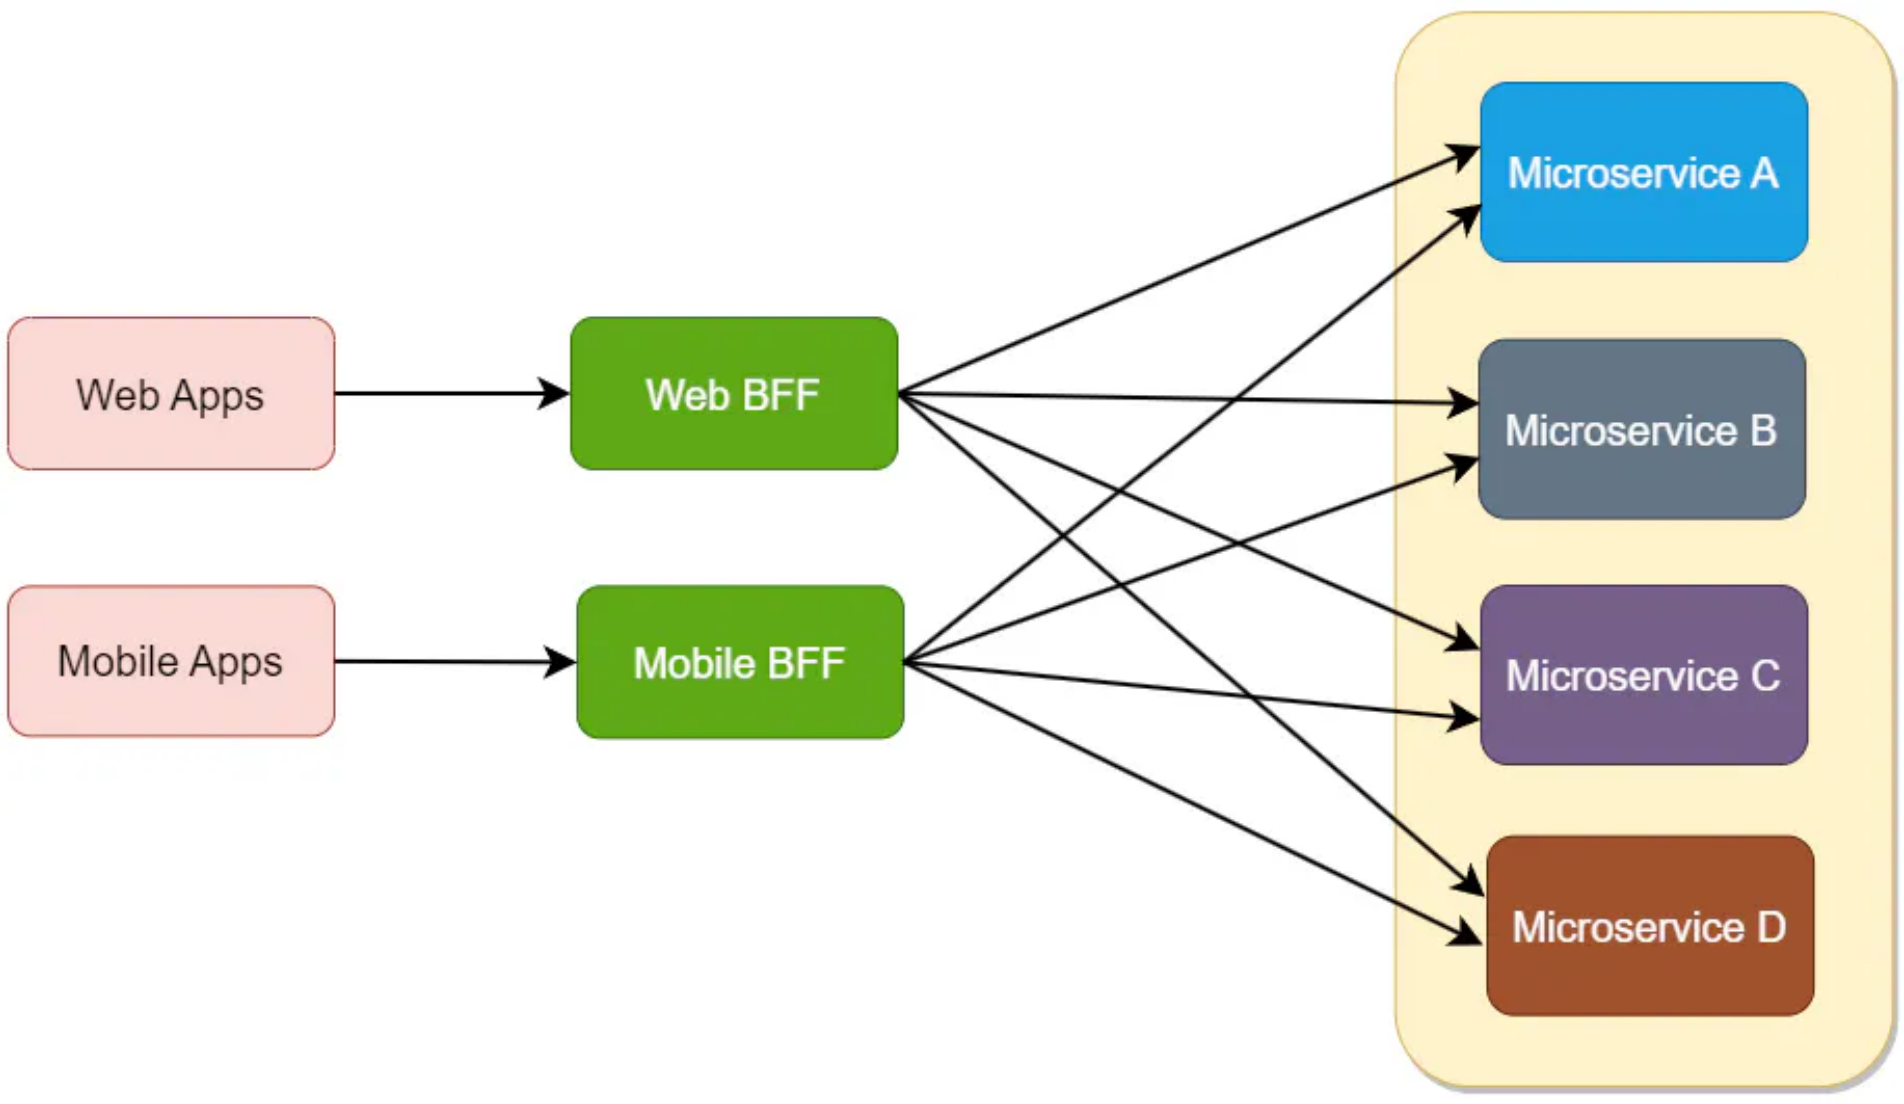

The architecture of the BFF pattern primarily consists of individual backends (the BFFs), each catering to a specific frontend. These BFFs, in turn, communicate with the underlying microservices to fetch the required data.

Let's break down this structure:

1. **Frontend Applications**: These are the various user-facing applications, such as desktop, mobile, or web applications. They are like the customers ordering from a menu in a restaurant.

2. **BFFs (Backends for Frontends)**: Each BFF is paired with a specific frontend application, catering to its unique requirements. They are like the chefs preparing each dish according to a customer's preferences.

3. **Microservices**: These are the underlying services that the BFFs interact with to fetch data. They are like the kitchen staff, providing the raw materials needed for each dish.

BFF Architecture

A Closer Look at BFFs

But what does a BFF (Backend for Frontend) actually do? It takes on several crucial responsibilities:

1. **Tailored Data Delivery**: Each BFF ensures that its paired frontend receives just the data it needs. It's like a filter, ensuring that the frontend isn't overwhelmed with unnecessary information.

2. **Streamlining Communication**: The BFF communicates with multiple microservices, consolidates the data, and presents it to the frontend in a streamlined manner. It's like an interpreter, translating a myriad of languages into one that the frontend understands.

3. **Handling Client-Specific Logic**: Each BFF can also handle logic specific to its frontend, relieving the client from complex computations. It's like a personal assistant, taking care of tasks to make the client's job easier.
